Fermilab
21 February 2008

- Basics of Shower Monte Carlo programs
- The POWHEG formalism
- Applications
- Conclusions
Frontier research in particle physics studies scattering and production of elementary constituents.

\[ e^+ e^- \rightarrow q\bar{q} \quad gg \rightarrow H \quad gg \rightarrow gg \]

Ideally, one needs elementary constituents as projectiles and targets, (i.e. a collider for leptons, gluons and quarks) and a final-state detector of leptons, gluons and quarks. Not obvious for quarks and gluons:

- at short distance, due to asymptotic freedom, quarks and gluons behave as free particles
- at long distance, infrared slavery: very strong interactions hide the simplicity of the description of the constituents.
Collinear-splitting processes in the initial and final state (always with transverse momenta \( > \Lambda_{\text{QCD}} \)) are strongly enhanced. This is due to the fact that, in perturbation theory, the denominators in the propagators are small.

- The algorithms that evaluate all these enhanced contributions are called shower algorithms.
- Shower algorithms give a description of a hard collision up to distances of order \( 1/\Lambda_{\text{QCD}} \).
- At larger distances, perturbation theory breaks down and we need to resort to non-perturbative methods (i.e. lattice calculations). However, these methods can be applied only to simple systems. The only viable alternative is to use models of hadron formation.
Color and hadronization

Shower Monte Carlo programs assign color labels to partons. Only color connections are recorded (in large $N_c$ limit). The initial color is assigned according to hard cross section.

Color assignments are used in the hadronization model.

Most popular models: Lund string model, cluster model.

In all models, color singlet structures are formed out of color connected partons, and are decayed into hadrons, preserving energy and momentum.
### Hadronic final states

</table>

High-energy experimental physicists feed this kind of output through their detector-simulation software, and use it to determine **efficiencies** for signal detection, and perform **background estimates**.

Analysis strategies are set up using these simulated data.
In high-energy collider physics not many questions can be answered without a Shower Monte Carlo (SMC).

The name shower comes from the fact that we dress a hard event with QCD radiation.

After a latency period, many physicists are now looking at shower Monte Carlo models again, under different perspective: Catani, Krauss, Kühn & Webber; Mangano, Moretti, Piccinini, Pittau, Polosa & Treccani; Frixione & Webber; Kramer, Mrenna, Nagy & Soper; Giele, Kosower & Skands; Bauer & Schwartz; Schumann & Krauss; Dinsdale, Ternick & Weinzierl; …

Shower algorithms summarize most of our knowledge in perturbative QCD: infrared cancellations, Altarelli-Parisi equations, soft coherence, Sudakov form factors. All have a simple interpretation in terms of shower algorithms.
“The Monte Carlo simulation has become the major mean of visualization of not only detector performance but also of physics phenomena. So far so good. But it often happens that the physics simulations provided by the Monte Carlo generators carry the authority of data itself. They look like data and feel like data, and if one is not careful they are accepted as if they were data.”

J.D. Bjorken

Talk given at the 75th anniversary celebration of the Max-Planck Institute of Physics, Munich, Germany, December 10th, 1992, as quoted in Beam Line, Winter 1992, Vol. 22, No. 4. Reference taken from Sjöstrand.
Shower basics: collinear factorization

QCD emissions are enhanced near the collinear limit.

Cross sections factorize near collinear limit

\[
\Phi_{n+1} = \Phi_n \Phi_r \\
\Phi_r \propto dt dz d\phi
\]

\[
|M_{n+1}|^2 \Phi_{n+1} \implies |M_n|^2 \Phi_n \frac{\alpha_s}{2\pi} \frac{dt}{t} P_{q,qg}(z) \frac{dz}{2\pi}
\]

\[
t : (k + l)^2, p_T^2, E^2 \theta^2 \ldots
\]

\[
z = \frac{k^0}{k^0 + l^0} : \text{energy (or } p_{\parallel} \text{ or } p^+) \text{ fraction of quark}
\]

\[
P_{q,qg}(z) = C_F \frac{1 + z^2}{1 - z} : \text{Altarelli-Parisi splitting function}
\]

(ignore \( z \to 1 \) IR divergence for now)
If another gluon becomes collinear, iterate the previous formula

\[ \theta', \theta \to 0 \text{ with } \theta' > \theta \]

Collinear partons can be described by a factorized integral ordered in \( t \).
Collinear factorization: multiple emissions

For \( n \) collinear emissions, the cross section goes as

\[
\sigma \approx \sigma_0 \alpha_s^n \int_{t_0}^{Q^2} \frac{dt_1}{t_1} \frac{dt_2}{t_2} \ldots \frac{dt_n}{t_n} \theta \left( Q^2 > t_1 > t_2 > \ldots > t_n > t_0 \right) 
\]

\[
= \sigma_0 \alpha_s^n \int_{t_0}^{Q^2} \frac{dt_1}{t_1} \int_{t_0}^{t_1} \frac{dt_2}{t_2} \ldots \int_{t_0}^{t_{n-1}} \frac{dt_n}{t_n} \approx \sigma_0 \alpha_s^n \frac{1}{n!} \left( \log \frac{Q^2}{t_0} \right)^n
\]

- \( Q^2 \) is an upper cutoff for the ordering variable \( t \)
- \( t_0 \approx \Lambda^2 \approx \Lambda_{\text{QCD}}^2 \) is an infrared cutoff (quark mass, confinement scale)
- Due to the log dependence, we call it leading-log approximation.
- According to the Kinoshita-Lee-Nauenberg theorem, the virtual corrections, order by order, contribute with a comparable term, with opposite sign.
- The virtual leading-log contribution should be included in order to get sensible results!
Typical dominant configuration at very high $Q^2$

$\gamma^* \rightarrow \text{hadrons}$

- Besides $q \rightarrow qg$, also $g \rightarrow gg$, $g \rightarrow q\bar{q}$ come into play.
- In the typical configurations, intermediate angles are of order of geometric average of upstream and downstream angles.
- Each angle is $O(\alpha_s)$ smaller than its upstream angle, and $O(\alpha_s)$ bigger than its downstream angle.
- As relative momenta become smaller, $\alpha_s$ becomes bigger, and this picture breaks down.
Simple probabilistic interpretation of “not-resolved” corrections

- probability of emission in the interval $dt$, at order $\alpha_s$ (multiple emissions are of higher orders in $\alpha_s$)

$$dP_{emis}(t + dt, t) = \frac{dt}{t} \frac{\alpha_s(t)}{2\pi} \int dz P_{i,jk}(z)$$

- probability of no emission in the interval $dt$

$$dP_{no\ emis}(t + dt, t) = 1 - dP_{emis}(t + dt, t) = 1 - \frac{dt}{t} \frac{\alpha_s(t)}{2\pi} \int dz P_{i,jk}(z)$$

The “no emission” probability contains, through the 1, all the virtual corrections (in the collinear approximation, that is at the leading-log level).
Simple probabilistic interpretation of “not-resolved” corrections

- divide a finite interval \([t_2, t_1]\) in \(N\) small intervals \(dt = (t_1 - t_2)/N\).

\[
\begin{array}{c}
\vdots \\
\hline
\vdots \\
\hline
\vdots \\
\hline
\vdots \\
\hline
\vdots \\
\end{array}
\]

\(t_2\) \hline \(t_n\) \hline \(t_1\) \hline \(dt\)

The probability of not emitting radiation between the two ordering scales \(t_1\) and \(t_2\) is given by the product

\[
P_{\text{no emis}}(t_1, t_2) = \lim_{N \to \infty} \prod_{n=1}^{N} \left[1 - \frac{dt}{t_n} \frac{\alpha_s(t_n)}{2\pi} \int dz P_{i,jk}(z)\right]
\]

\[
= \exp \left\{- \int_{t_2}^{t_1} \frac{dt}{t} \frac{\alpha_s(t)}{2\pi} \int dz P_{i,jk}(z)\right\}
\]

\[
\equiv \Delta(t_1, t_2)
\]

- The weight \(\Delta(t_1, t_2)\) is called Sudakov form factor. It resums all the dominant virtual corrections to the tree graph (in the collinear approximation).
\[ \Delta_i(t_1, t_2) = \exp \left\{ -\sum_{jk} \int_{t_2}^{t_1} \frac{dt}{t} \frac{\alpha_s(t)}{2\pi} \int dz \, P_{i,jk}(z) \right\} \]

Notice that, when \( t_2 \ll t_1 \), \( \Delta \to 0 \), i.e. the probability that a hard parton turns into a narrow jet, or that it does not radiate at all, is small (it is Sudakov suppressed)
The probability of the first branching is independent of subsequent branchings because of Kinoshita-Lee-Nauenberg cancellation. It is given by

$$dP_{\text{first}} = \Delta_i(t, t') \frac{\alpha_S(t')}{2\pi} \frac{dt'}{t'} P_{i,jk}(z) dz \frac{d\varphi}{2\pi}$$

Upon integrating in $z$ and $\varphi$, and summing over $jk$, we have

$$dP_{\text{first}} = \Delta_i(t, t') \frac{\alpha_S(t')}{2\pi} \frac{dt'}{t'} \int \sum_{(jk)} P_{i,jk}(z) dz \frac{d\varphi}{2\pi} = d\Delta_i(t, t')$$

i.e. the distribution is uniform in the Sudakov form factor.

The integral over the whole $t'$ range, from the minimum value $t_0$ (IR cutoff) up to $t$, is given by

$$\int_{t_0}^{t} dP_{\text{first}} = \int_{t_0}^{t} d\Delta_i(t, t') = \Delta_i(t, t) - \Delta_i(t, t_0) = 1 - 0 = 1$$

as it should be for a correct probabilistic interpretation.
\[ S_i(t, E) = \Delta_i(t, t_0) \mathbb{1} + \sum_{(jk)} \int_{t_0}^{t} \frac{\alpha_s(t')}{2\pi} \frac{dt'}{t'} \int dz \int d\varphi \frac{\Delta_i(t, t')}{2\pi} P_{i,jk}(z) S_j(t', zE) S_k(t', (1 - z)E) \]

- consider all tree graphs.
- assign values to the radiation variables \( \Phi_r(t, z \text{ and } \varphi) \) to each vertex.
- at each vertex, \( i \to jk \), include a factor

\[ \frac{dt}{t} \frac{dz}{2\pi} \frac{\alpha_s(t)}{2\pi} P_{i,jk}(z) \frac{d\varphi}{2\pi} \]
Final recipe II

- include a factor $\Delta_i(t_1, t_2)$ to each internal parton $i$, from hardness $t_1$ to hardness $t_2$.

$$\Delta_i(t_1, t_2) = \exp \left[ - \sum_{(jk)} \frac{1}{t} \frac{\alpha_S(t)}{2\pi} \int dz P_{i,jk}(z) \int d\phi \right]$$

The weights $\Delta_i(t_1, t_2)$ are called **Sudakov form factors**. They resum all the **dominant virtual corrections** to the tree graph (in the collinear approximation). Notice also that the inclusion of real and virtual corrections gives a net result of 1 (cancellation of collinear singularities in inclusive quantities).

- include a factor $\Delta_i(t, t_0)$ on final lines ($t_0 = \text{IR cutoff}$)

Actual implementation of the shower algorithm

We start from a given value of the ordering variable $t$. We want to generate the value $t'$ for the next emission, according to the probability

$$dP_{\text{first}} = \Delta_i(t, t') \frac{\alpha_s(t')}{2\pi} \frac{dt'}{t'} \int \sum_{(jk)} P_{i,jk}(z) \frac{d\varphi}{2\pi} = d\Delta_i(t, t')$$

Since this is an exact differential form, we proceed as in the case we want to generate a random variable $x$ according to a distribution function $f(x)$, whose indefinite integral is known, starting from a uniform random variable $r$

$$dP = f(X) \, dX = 1 \, dR \quad \text{where} \quad f(X) \, dX = dF(X)$$

$$\int_{x_{\text{min}}}^{x} f(X) \, dX = F(x) = \int_{0}^{r} 1 \, dR = r \quad \Rightarrow \quad x = F^{-1}(r)$$
Actual implementation of the shower algorithm

✓ generate a hard process configuration with a probability proportional to its parton-level cross section. Parton densities are evaluated at the typical “high” scale $Q$ of the process.

✓ for each final-state colored parton, generate a shower
  - set $t = Q^2$
  - generate a uniform random number $0 < r < 1$
  - solve the equation $\Delta_i(t, t') = r$ for $t'$
  - if $t' < t_0$ stop here (final state line). Begin hadronization
  - if $t' > t_0$, generate $z, jk$ with probability $P_{i,jk}(z)$, and $0 < \varphi < 2\pi$ uniformly. Assign energies $E_j = zE_i$ and $E_k = (1 - z)E_i$ to partons $j$ and $k$. The angle $\theta$ between their momenta is fixed by $t'$ and with $\varphi$ their direction is completely specified
  - restart shower from each of the two branched parton $j$ and $k$, setting the ordering parameter $t = t'$. 

![Diagram showing the shower algorithm](image)
for each initial-state colored parton, generate a shower in a similar way, but using a „trick”: the backward evolution (Sjöstrand)

\[
\frac{f_i^h(t', x) \Delta(t, t')}{f_i^h(t, x)} = r
\]

where \(f_i^h\) is the parton density for the colliding hadron \(h\), where parton \(i\) carries a momentum fraction \(x = E_i / E_h\)

Some momentum reshuffling is needed in order to preserve local (at each vertex) and global momentum conservation
Accuracy: soft divergences and double-log regions

\( z \to 1 \) \((z \to 0)\) region problematic. In fact, for \( z \to 1 \), \( P_{qq}, P_{gg} \div 1/(1 - z) \)

The choice of the ordering variable \( t \) makes a difference

\[
\text{virtuality: } t \equiv E^2 z(1 - z) \left(\theta^2\right) \\
\text{virtuality: } z(1 - z) > t/E^2 \quad \Rightarrow \quad \int \frac{dt}{t} \int_{\sqrt{t/E}}^{1-\sqrt{t/E}} \frac{dz}{1-z} \approx \frac{1}{4} \log^2 \frac{t}{E^2}
\]

\[
\text{virtuality: } z^2(1 - z)^2 > t/E^2 \quad \Rightarrow \quad \int \frac{dt}{t} \int_{t/E^2}^{1-t/E^2} \frac{dz}{1-z} \approx \frac{1}{2} \log^2 \frac{t}{E^2}
\]

\[
\text{angle: } \Rightarrow \quad \int \frac{dt}{t} \int_0^1 \frac{dz}{1-z} \approx \log t \log \Lambda
\]

Sizable difference in double-log structure!
Mueller (1981) showed that angular ordering is the correct choice

\[ \frac{d\theta}{\theta} \frac{\alpha_s \left( p_T^2 \right)}{2\pi} P(z) \, dz \]

\[ \theta_1 > \theta_2 > \theta_3 \ldots \]

\[ p_T^2 = E^2 z^2 (1 - z)^2 \theta^2 \]

\( \alpha_s(p_T^2) \) for a correct treatment of charge renormalization in soft region \( (p_T^2 \) equals to the maximum virtuality of the gluon line).

\[ \Delta_i(t, t') = \exp \left[ - \int_{t'}^t \frac{dt}{t} \int_{\sqrt{t_0/t}}^{1-\sqrt{t_0/t}} dz \frac{\alpha_s(p_T^2)}{2\pi} \sum_{(jk)} P_{i,jk}(z) \right] \]

\[ \approx \exp \left\{ - \frac{c_i}{4\pi b_0} \left[ \log \frac{t}{\Lambda^2} \log \frac{\log \frac{t}{\Lambda^2}}{\log \frac{t_0}{\Lambda^2}} - \log \frac{t}{t_0} \right]_{t'} \right\} \quad (c_q = C_F, c_g = 2C_A) \]

Sudakov dumping stronger than any power of \( t \).
Color coherence

Soft gluons emitted at large angles from final-state partons add coherently.

\[
\sum \text{emissions from all final lines}
\]

- angular ordering accounts for soft gluon interference.
- intensity for photon jets = 0
- intensity for gluon jets = \( C_A \) instead of \( 2C_F + C_A \)

In angular-ordered shower Monte Carlo, large-angle soft emission is generated first.

**Hardest emission**, i.e. highest \( p_T = E z(1 - z) \theta \), in general, happens later.
Some available codes

- **COJETS** Odorico (1984)
- **ISAJET** Paige+Protopopescu (1986)
- **FIELD AJET** Field (1986)
- **JETSET** Sjöstrand (1986)
- **HERWIG** Marchesini+Webber (1988),
  Marchesini+Webber+Abbiendi+Knowles+Seymour+Stanco (1992)
- **ARIADNE** Lönnblad (1992)
One can realistically aim at

leading collinear, leading double log, leading soft in large-$N_c$ limit

Soft effects for finite $N_c$ require matrix exponentiation in the Sudakov form factor.
New developments

- Interfacing Matrix Elements (ME) generators with Parton Showers: CKKW matching [Catani, Krauss, Küen, Webber], MLM matching [Mangano]

- Interfacing NLO calculations with Parton Showers: MC@NLO [Frixione, Webber], POWHEG [Nason]

Several other approaches have appeared

- $e^+e^- \rightarrow 3$ partons [Kramer, Mrenna, Soper]

- Shower by antenna factorization [Giele, Kosower, Skands]

- Shower by Catani-Seymour dipole factorization [Schumann, Krauss]

- Shower with quantum interference [Nagy, Soper]

- Shower by Soft Collinear Effective Theory [Bauer, Schwartz]

- Shower from the dipole formalism [Dinsdale, Ternick, Weinzierl]

Up to now, complete results for hadron colliders only from MC@NLO and POWHEG.
LO-ME good for shapes. Uncertain absolute normalization

\[ \alpha_s^n(2\mu) \approx \alpha_s^n(\mu) (1 - b_0 \alpha_s(\mu) \log(4))^n \approx \alpha_s^n(\mu) (1 - n\alpha_s(\mu)) \]

For \( \mu = 100 \text{ GeV} \), \( \alpha_s = 0.12 \), normalization uncertainty:

<table>
<thead>
<tr>
<th></th>
<th>( W + 1J )</th>

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>( \pm 12% )</td>
<td>( \pm 24% )</td>
<td>( \pm 36% )</td>
</tr>
</tbody>
</table>

To improve on this, we need to go to NLO

- **Positive experience** with NLO calculations at LEP, HERA and Tevatron
- NLO results are cumbersome to compute: typically made up of an \( n \)-body (Born + virtual + soft and collinear remnants) and \( (n + 1) \)-body (real emission) terms, both divergent (finite only when summed up).
- **Merging NLO with shower** is a natural extension of present approaches.
NLO + Parton Shower

The main problem in merging a NLO result and a Parton Shower is not to double-count radiation: the shower might produce some radiation already present at the NLO level.

LO:  

NLO:
POWHEG: how it works

1. **POWHEG**, **POsitive Weight Hardest Emission Generator**, [Nason, hep-ph/0409146], generates first a partonic event with just one single emission, at NLO level, and with the correct weight in order not to have double-counting coming from (subsequent) radiation. The $p_T$ of the produced radiation works as an upper cutoff for the $p_T$'s of the entire subsequent shower.

2. The event is written on a file using the standard Les Houches Interface and is processed by the Parton Shower program (HERWIG, PYTHIA…), that showers the event, but with a $p_T$ less than the $p_T$ generated by POWHEG ($p_T$ veto).
   - if the shower is ordered in $p_T$ (for example PYTHIA), nothing else needs to be done
   - if the shower is ordered in angle (for example HERWIG), we need to generate correctly soft radiation at large angle.
     - pair up the partons that are nearest in $p_T$
     - generate an angular-ordered shower associated with the paired parton, stopping at the angle of the paired partons (truncated shower)
     - generate all subsequent vetoed showers
Example of truncated shower: $e^+e^-$

- nearby partons: 1 and 2
- truncated shower: 1 and 2 pair, from $\theta$ up to a maximum angle. The truncated shower reintroduces coherent soft radiation from 1 and 2 at angles larger than $\theta$ (angular-ordered shower Monte Carlo programs generate those earlier).
- 1 and 2 shower from $\theta$ to cutoff
- 3 showers from maximum to cutoff

Truncated showers not yet implemented.

No evidence of effects from their absence in $ZZ$ and $e^+e^-$ production. Might be some effects in heavy-quark production.
We can always parametrize the \((n + 1)\)-body phase space \(\Phi_{n+1}\) in terms of the Born phase space \(\Phi_n\) and three radiation variables \(\Phi_r\): \(\Phi_{n+1} = \{\Phi_n, \Phi_r\}\)

\[
\langle O \rangle = \int O \, d\sigma = \int d\Phi_n \, O(\Phi_n) \left[ B(\Phi_n) + V_b(\Phi_n) \right] + \int d\Phi_n \, d\Phi_r \, O(\Phi_n, \Phi_r) \, R(\Phi_n, \Phi_r)
\]

where \(V_b\) is the (divergent) virtual differential cross section. The virtual and real-radiation integrals are separate divergent. Their sum is finite (for any infra-red safe observable).

A typical subtraction method re-organize the integrals in the form

\[
\langle O \rangle = \int d\Phi_n \, O(\Phi_n) \left[ B(\Phi_n) + V(\Phi_n) \right] + \int d\Phi_n \, d\Phi_r \left[ O(\Phi_n, \Phi_r) \, R(\Phi_n, \Phi_r) - O(\Phi_n) \, C(\Phi_n, \Phi_r) \right]
\]

Defining

\[
V(\Phi_n) = V_b(\Phi_n) + \int d\Phi_r \, C(\Phi_n, \Phi_r) \quad \Leftarrow \text{finite}
\]

we have

\[
\langle O \rangle = \int d\Phi_n \, O(\Phi_n) \left[ B(\Phi_n) + V(\Phi_n) \right] + \int d\Phi_n \, d\Phi_r \left[ O(\Phi_n, \Phi_r) \, R(\Phi_n, \Phi_r) - O(\Phi_n) \, C(\Phi_n, \Phi_r) \right]
\]
Shower Monte Carlo (SMC) cross section for first emission \( (d\Phi_r = dt \, dz \, d\varphi) \)

\[
\langle O \rangle = \int d\Phi_n \, B(\Phi_n) \left\{ O(\Phi_n) \Delta t_0 + \int_{t_0}^t \frac{dt}{t} \, dz \, d\varphi \, O(\Phi_n, \Phi_r) \, \Delta t \frac{\alpha_s}{2\pi} \, P(z) \right\}
\]

with

\[
\Delta t = \exp \left[ -\int_t^{t'} \frac{dt'}{t'} \, dz' \, d\varphi' \, \frac{\alpha_s}{2\pi} \, P(z') \right]
\]

The expansion at order \( \alpha_s \) gives the NLO_{SMC}

\[
\langle O \rangle = \int d\Phi_n \, B(\Phi_n) \left\{ O(\Phi_n) + \int_{t_0}^t \frac{dt}{t} \, dz \, d\varphi \, [O(\Phi_n, \Phi_r) - O(\Phi_n)] \frac{\alpha_s}{2\pi} \, P(z) \right\}
\]

This is the inexact NLO correction implemented by the SMC

How do we reach exact NLO accuracy?
Towards NLO accuracy

\[ \langle O \rangle = \int d\Phi_n O(\Phi_n) [B(\Phi_n) + V(\Phi_n)] \]
\[ + \int d\Phi_n d\Phi_r [O(\Phi_n, \Phi_r) R(\Phi_n, \Phi_r) - O(\Phi_n) C(\Phi_n, \Phi_r)] \]
\[ = \int d\Phi_n O(\Phi_n) \left\{ B(\Phi_n) + V(\Phi_n) + \int d\Phi_r [R(\Phi_n, \Phi_r) - C(\Phi_n, \Phi_r)] \right\} \]
\[ + \int d\Phi_n d\Phi_r R(\Phi_n, \Phi_r) [O(\Phi_n, \Phi_r) - O(\Phi_n)] \]

Define

\[ \overline{B}(\Phi_n) = B(\Phi_n) + V(\Phi_n) + \int d\Phi_r [R(\Phi_n, \Phi_r) - C(\Phi_n, \Phi_r)] \]

\[ \langle O \rangle = \int d\Phi_n O(\Phi_n) \overline{B}(\Phi_n) + \int d\Phi_n d\Phi_r R(\Phi_n, \Phi_r) [O(\Phi_n, \Phi_r) - O(\Phi_n)] \]

In NLO_{SMC}, it was

\[ \langle O \rangle = \int d\Phi_n O(\Phi_n) B(\Phi_n) + \int d\Phi_n d\Phi_r B(\Phi_n) \frac{\alpha_s}{2\pi} P(z) \frac{1}{t} \left[ O(\Phi_n, \Phi_r) - O(\Phi_n) \right] \]
NLO_{SMC} \leftrightarrow \text{NLO} : \quad B(\Phi_n) \leftrightarrow \overline{B}(\Phi_n) \quad B(\Phi_n) \frac{\alpha_s}{2\pi} P(z) \frac{1}{t} \leftrightarrow R(\Phi_n, \Phi_r)

All-order emission probability in SMC

\langle O \rangle = \int d\Phi_n B(\Phi_n) \left\{ O(\Phi_n) \Delta t_0 + \int_{t_0} d\Phi_r O(\Phi_n, \Phi_r) \Delta t \frac{\alpha_s}{2\pi} P(z) \frac{1}{t} \right\}

with

\Delta t = \exp \left[ - \int d\Phi'_r \frac{\alpha_s}{2\pi} P(z') \frac{1}{t'} \theta(t' - t) \right]

All order emission probability in POWHEG

\langle O \rangle = \int d\Phi_n \overline{B}(\Phi_n) \left\{ O(\Phi_n) \Delta t_0 + \int d\Phi_r O(\Phi_n, \Phi_r) \Delta t \frac{R(\Phi_n, \Phi_r)}{B(\Phi_n)} \right\}

\Delta t = \exp \left[ - \int d\Phi'_r \frac{R(\Phi_n, \Phi'_r)}{B(\Phi_n)} \theta(t' - t) \right]

with \( t = k_T(\Phi_n, \Phi_r) \) = transverse momentum of the emitted parton.

\textbf{POSITIVE} if \overline{B} is positive (i.e. NLO < LO).
POWHEG’s Sudakov form factor has the form (with $c \approx 1$)

$$\Delta_t = \exp \left[ - \int_t^{Q^2} \frac{d k_T^2}{k_T^2} \frac{\alpha_s(c k_T^2)}{\pi} \left\{ A \log \frac{E^2}{k_T^2} + B \right\} \right]$$

The next-to-leading log (NLL) Sudakov form factor has the form

$$\Delta_t^{\text{NLL}} = \exp \left[ - \int_t^{Q^2} \frac{d k_T^2}{k_T^2} \frac{\alpha_s(k_T^2)}{\pi} \left\{ \left( A_1 + A_2 \frac{\alpha_s(k_T^2)}{\pi} \right) \log \frac{E^2}{k_T^2} + B \right\} \right]$$

provided the color structure of the process is sufficiently simple ($\leq 3$ colored legs). Can use this to fix $c$ in POWHEG’s Sudakov form factor as suggested in Catani, Webber, Marchesini, (1991). HERWIG uses this.

For colored legs $\geq 4$, exponentiation only holds at leading-log (LL) or LL + NLL in the large-$N_c$ limit (i.e. planar color structure of Feynman diagrams)

POWHEG’s Sudakov form factor is always LL accurate. NLL accurate for $\leq 3$ colored legs, NLL accurate in leading $N_c$ in all cases.
To generate the underlying Born variables ($\Phi_n$), distributed according to $\overline{B}(\Phi_n)$, one uses programs like BASES/SPRING, that, after a single integration, can generate points distributed according to the integrand function.

Use the veto technique and the highest-$p_T$ bid procedure, to generate the radiation variables, distributed according to $d\Delta_i(t, t')$.

These tricks are well known to Monte Carlo experts.

We have collected a few of them in the appendixes of our paper [Frixione, Nason and C.O., arXiv:0709.2092 [hep-ph]].
POsitive-Weight Hardest Emission Generator

✓ it is independent from parton-shower programs. POWHEG can be interfaced with both PYTHIA and HERWIG, or with your favorite showering program, if the vetoed shower is implemented, according to the Les Houches Interface.

✓ it can use existing NLO results

✓ it generates events with positive weights

✓ As far as the hardest emission is concerned, POWHEG guarantees:
  • NLO accuracy on integrated quantities
  • collinear, double-log (soft-collinear), large-$N_c$-soft single-log of the Sudakov (in fact, corrections that exponentiates are obviously OK)

✓ As far as subsequent (less hard) emissions, the output has the accuracy of the SMC one is using.

✗ no truncated shower implemented up to now. But this is a problem that affects all the angular-ordered SMC when the shower is initiated by a relatively complex matrix element.
Existing implementations

The POWHEG method has already been **successfully** used in

- **ZZ production** [Nason and Ridolfi, hep-ph/0606275]
- **$e^+e^-$ to hadrons** [Latunde-Dada, Gieseke and Webber, hep-ph/0612281]
- **heavy-quark $Q\bar{Q}$ production** ($c\bar{c}$, $b\bar{b}$, $t\bar{t}$) with **spin correlations** [Frixione, Nason and Ridolfi, arXiv:0707.3088 [hep-ph]].

The POWHEG programs for ZZ and $Q\bar{Q}$ production have been interfaced to both **PYTHIA** and **HERWIG**.

- **single vector-boson production** (with spin correlations), **vector-boson production** plus jet and **Higgs boson production via vector-boson fusion** is **work in progress** [Alioli, Nason, Oleari and Re]
ZZ production: POWHEG + HERWIG vs MC@NLO

No significant difference with MC@NLO [Nason and Ridolfi, hep-ph/0606275]
Agreement between POWHEG + HERWIG and POWHEG + PYTHIA

[Nason and Ridolfi, hep-ph/0606275]
Fit to $e^+e^-$ data: better agreement than in the standard matrix-element correction approach.

[Latunde-Dada, Gieseke and Webber, hep-ph/0612281]
$t\bar{t}$ production: POWHEG vs. NLO

- when $p_T^{t\bar{t}} \to 0$, POWHEG treats correctly the resummation of soft/collinear radiation
- when $p_T^{t\bar{t}}$ becomes large, POWHEG approaches the NLO result
- when $\Phi_{t\bar{t}} \to 0$, the emitted radiation becomes hard and POWHEG goes to the NLO result.
Good agreement for all observables considered. There are sizable differences that can be ascribed to different treatment of higher terms. But more investigation needed (different scale choices, no truncated shower, different hard/soft radiation emission, ...).
ALPGEN can generate samples of $t\bar{t} + n$ jets. Can be compared to NLO + Parton Shower [Mangano, Moretti, Piccinini & Treccani, hep-ph/0611129]

✓ advantage: better high jet multiplicity (exact Matrix Element)

✗ disadvantage: worse normalization (no NLO)

ALPGEN

- Generation: $p_{T\text{min}} = 30 \text{ GeV}, \quad \Delta R = 0.7$
- Matching: $E_{T\text{min}} = 30 \text{ GeV}, \quad \Delta R = 0.7$

Jet definitions

- Tevatron: $E_{T\text{min}} = 15 \text{ GeV}, \quad \Delta R = 0.4, \quad K \text{ factor} = 1.45$
- LHC: $E_{T\text{min}} = 20 \text{ GeV}, \quad \Delta R = 0.5, \quad K \text{ factor} = 1.57$
Rapidity $y_1$ of the leading jet (highest $p_T$).

Different shapes both at Tevatron and at the LHC
POWHEG’s distribution as in ALPGEN: no dip present. The size of discrepancy can be attributed to different treatment of higher-order terms. Is this “feature” really there?
The new $pp \to t\bar{t} + \text{jet}$ at NLO [Dittmaier, Uwer, Weinzierl, hep-ph/0703120] shows no dip too (preliminary result).
POWHEG is a method, NOT (only) a set of programs!

POWHEG is fully general and can be applied to any NLO subtraction framework.

We have provided any user with all the formulae and ingredients to implement an existing NLO calculation in the POWHEG formalism [Frixione, Nason and C.O., arXiv:0709.2092 [hep-ph]].

We have looked in detail at POWHEG in two subtraction schemes:

- the Frixione, Kunszt and Signer scheme
- the Catani and Seymour scheme.

We have discussed, in a pedagogical way, two examples:

- $e^+e^- \rightarrow q\bar{q}$
- $q\bar{q} \rightarrow V$

The fortran implementation of the POWHEG code for these two processes can be found at:

http://moby.mib.infn.it/~nason/POWHEG/FNOpaper/
Strategy and conclusions

✓ Shower Monte Carlo programs to do the final shower already exist
✓ Most of them implement a $p_T$ veto
✓ Most of them comply with a standard interface to hard processes, the so-called Les Houches Interface (LHI)

SO…

• construct a POWHEG for a NLO process. Output on LHI
• if needed, construct a generator capable to add truncated showers to events from the LHI. Output again on LHI
• use standard Shower Monte Carlo to perform the $p_T$-vetoed final shower from the event on LHI.
